Q2 - Regression

Weizhuo Wang 2/23/2020

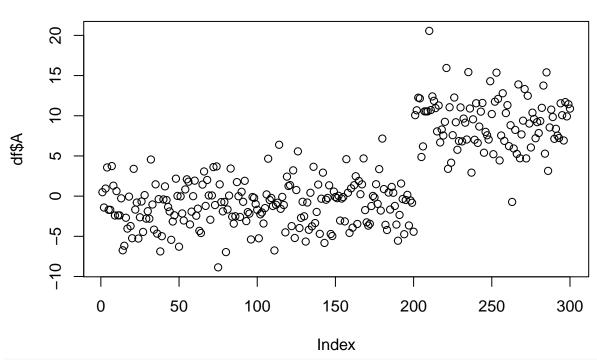

Check missing values and variable distribution.

sum(is.na(df))

[1] 0

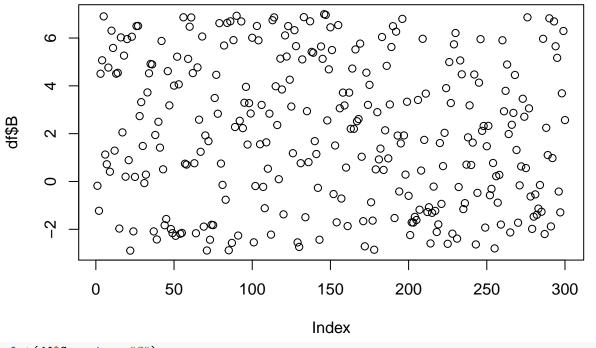

plot(df\$A, main = "A")

Α

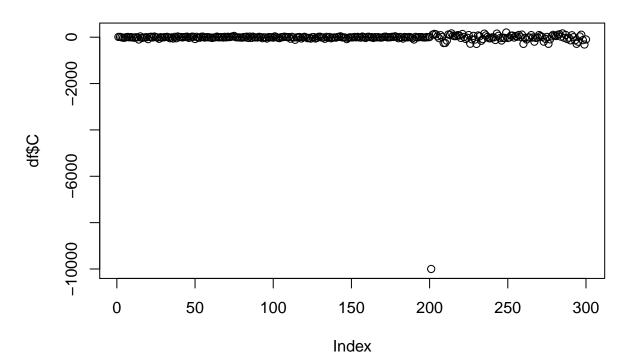

plot(df\$B, main = "B")

В

plot(df\$C, main = "C")

C

By checking on distributions, there is a potential outlier.

First fit a simple linear regression as initial model.

```
mod0 = lm(C \sim A + B, data = df)

```

Regression model looks better, and there is no correlation between independent variables, can then start refining model.

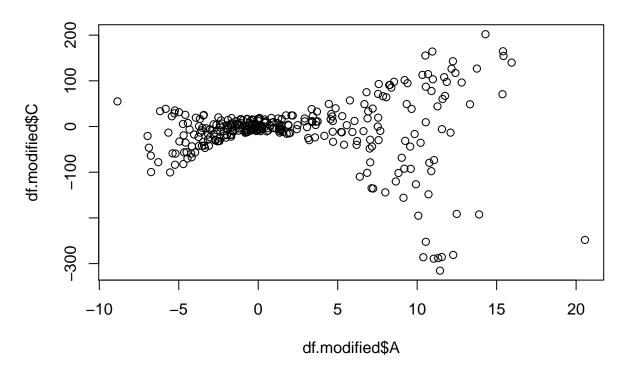

plot(df.modified\$C, main = "C")

C

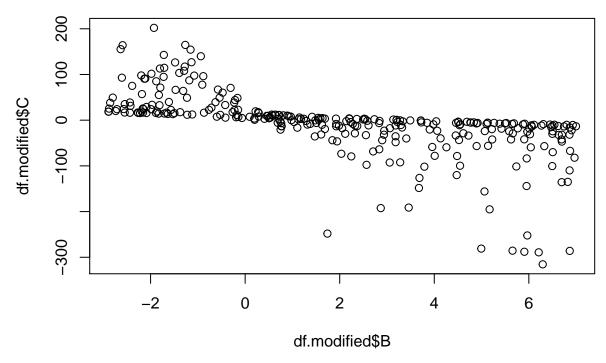

plot(df.modified\$A, df.modified\$C, main = "A vs. C")

A vs. C

```
plot(df.modified$B, df.modified$C, main = "B vs. C")
```

B vs. C

Also notice a pattern change on variable C after 200 observations. To solve this, I create time variable (called t) to indicate the time of a point being recorded.

For both independent variables, relation to C changes at point 0, therefor a dummy variable representing positive or negative may be useful (IA and IB respectively, with 1 means negative value of that variable).

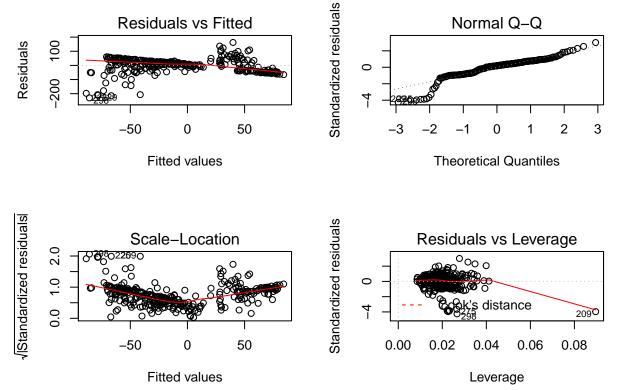

```
df.modified$t = c(1:nrow(df.modified))
df.modified$IA = as.factor(ifelse(df.modified$A<0, "1", "0"))
df.modified$IB = as.factor(ifelse(df.modified$B<0, "1", "0"))</pre>
```

Fit model with all variables.

```
mod2 = lm(C ~ ., df.modified) # put everything into expaintory variable
summary(mod2)
```

```

```

Model performance is not very satisfactory. Here are some thoughts:

- the negative value of A or B can inflence the other, add interaction of A*B or A*IB may help explain more variance. However, adding both interaction forms may cause overfitting
- time variable t influences all other independent variables, so we can add interaction of t and all others

With the above ideas, add all variables and their interactions into a full model, then use model selection method (BIC) to choose important features.

```
# this is the full model
# use BIC method to reduce the size of full model
mod3 = lm(C ~ A*B*t*IA*IB, df.modified)
mod3.re = MASS::stepAIC(mod3, direction = "backward", k = log(nrow(df.modified)), trace = 0)
summary(mod3.re)

plot(mod3.re)
```

The selected model performance is excellent, it expains about 97% variation in variable C. However, there may exist overfitting.

Even the redeuced model still has tons of variables, intuitively, some variables seem not neccessay. For example the interaction term between time and IA, time variable will use anyway no matter A takes positive or negative value. Therefore, I would delete some interaction terms regarding IA and IB and run model selection again.

```
# this is the intuition model, again use BIC
mod4 = lm(C \sim A*B*t + IA:A + IA:B + IB:A + IB:B + A:B:IA + A:B:IB, data = df.modified)
mod4.re = MASS::stepAIC(mod4, direction = "backward", k = log(nrow(df.modified)), trace = 0)

```

So this time, the model fits the data perfectly without being too complecated, diagnosis plots are reseasonablely acceptable.

Also notice that time variable is not used in the final model. Again, IB seems not useful, so try to delete more interaction terms to see result.

```

This model is more ideal in terms of performance and interpretability with all diagnosis plots generally valid. Therefore, I choose it as my final regression mode. The model is written as

$$C = \beta_0 + \beta_1 A + \beta_2 B + \beta_3 A * B + \beta_4 A * B * I_A + \epsilon$$
